BACKGROUND

This memo has been prepared in response to a October 9, 2020 request for additional information from Fisheries and Oceans Canada (DFO) regarding the potential reduction in flow from Moose River, that may have occurred as a result of the existing Touquoy Gold Mine open pit. A survey was conducted previously on July 30, 2020 on the section of Moose River beginning at surface water monitoring station SW-2 and extending downstream 650 m (Stantec 2020). This memo summarizes additional fish habitat surveys which were completed within Moose River in the vicinity of the existing open pit.

METHODS

For the purposes of the fish habitat surveys conducted in 2020, Moose River was divided into three reaches; the upper reach extending downstream of Mooseland Road to SW-2, the middle reach extending from SW-2 downstream 650 m, and the lower reach extending from 650 m downstream to the confluence with Otter Dam Flowage (Attachment A). Fish habitat surveys were conducted in the upper and lower section of Moose River on November 2 to 4, 2020.

Fish habitat information was collected on a habitat type scale and included: habitat type (riffle, run, pool), substrate composition, bank stability, riparian vegetation, overhead and instream cover, wetted and channel width, depth and gradient. Incidental observations of salmonid redds, preferred spawning habitat, groundwater seepage and potential “areas of interest” were noted. For the purposes of this report, the areas of interest defined as locations where a natural barrier to fish passage could occur as a result of low flows (i.e., bedrock intrusion or the channel geometry was shallow across its entire width). Data were collected using a proprietary Electronic Aquatic Utility (EAU) which included georeferenced data collection and photos of habitat via iPhone (accuracy less than <9.1 m).

The in situ water quality parameters measured included: water temperature, dissolved oxygen, and conductivity (all measured using a YSI ProPlus meter) and pH (measured using a Hanna Instruments 98127 pH meter or YSI ProDSS, which also included turbidity). Water quality meters were calibrated daily or as required. In situ water quality results were compared to the Canadian Water Quality Guidelines for Protection of Aquatic Life Freshwater (CWQG PAL) (CCME 2014).

RESULTS

Water levels were relatively high at the time of the survey due to recent heavy rain and snow fall, and limited the area that was safely wadable for obtaining fish habitat information (i.e., at or above bankfull depth). The water was clear, however stained with tannins which made visibility of substrate difficult in some places (e.g., limited visibility to less than 0.7m). Given the water flow, fish habitat assessment was typically conducted from the edge of shore or along the edge of the bank. Substrates were visually classified where visibility through the water was good and it was safe to wade. Where visibility was poor or water depths/velocities made wading unsafe the composition of substrate was classified based on feel using the bottom of a boot, by poking with a long stick, or a combination of both.

No redds were observed and no areas of preferable Atlantic salmon spawning habitat were observed in the upper and lower reach; however, these observations were limited by visibility.

The upper reach consisted of mainly riffle-run habitats. At the time of the fish habitat survey the average wetted width was 11.2 m (range 4 to 40 m) and average bankfull width was 12.5 m (4.8 to 40 m). Water depths in the main channel ranged from 0.10 to over 1.5 m. Banks were stable and riparian vegetation was dominated by trees (~60%) and grasses (~20%). Substrate was dominated by cobble and fines (~30% each respectively). Overhead and instream cover was generally low (<5% and ~20%, respectively). Instream cover was made up primarily of submergent aquatic vegetation (~15%). Representative photos are provided in Appendix B (Appendix B, Photos 1-32).

Within the upper reach, Moose River is typically one channel with braiding approximately 50 m downstream of Mooseland Road for approximately 90 m (Appendix B, Photos 3-10). One other small braid was observed approximately 100 m upstream of SW-2 (Appendix B, Photo 30). Three potential areas of interest (AOI)s in the upper reach (AOI-3, AOI-4, AOI-5; Appendix B, Photos 6, 24 and 29), in addition to two AOIs identified in July (AOI-1, and AOI-2; Stantec 2020) and three areas of potential groundwater seepage were observed (Appendix B, Photos 46 to 48).

The lower reach consisted of mainly deep run and pool habitats. At the time of the fish habitat survey the average wetted width of the main channel was 18.4 m (range 9.25 to 35) and average bankfull width was 18.5 m (9.3 to 35 m). Water depths ranged from 0.3 to over 1.6 m. Banks were stable and riparian vegetation was dominated by trees (~50%) and shrubs (~35%). Substrate was dominated by a fines (~55%). Overhead and instream cover was generally low (<5% and ~20%, respectively). Instream cover was made up primarily of submergent aquatic vegetation (~15%). Representative photos are provided in Appendix B (Appendix B, Photos 33-45). No potential AOIs were observed and one area of potential groundwater seepage was observed (Appendix B, Photo 49).

Water temperature at the time of sampling in both the upper and lower reach ranged from 4.6 to 9.0°C and conductivity ranged from 29.2 to 32.0 µS/cm (Attachment C, Table C.2). Dissolved oxygen concentrations ranged from 10.9 to 12.5 mg/L. They were above the CWQG PAL recommended minimum value of 9.5 mg/L for early life stages (CCME 2014). Turbidity ranged from 1.38 to 1.46 for the locations sampled and is considered low. The pH ranged from 3.9 to 4.9 and was below the CWQG PAL recommended range (6.5 – 9.0). The ranges of pH observed in Moose River during the fall survey are considered to be generally unsuitable for Atlantic salmon (*Salmo salar*) and brook trout (*Salvelinus fontinalis*) (Stanley and Trial 1995; Raleigh 1982). The pH values observed have the potential to result in decreased hatching success for Atlantic salmon and brook trout (Haines 1981; Menendez 1976).

SUMMARY

Moose River in the vicinity of the existing open pit generally consists of a single channel, however some braiding was observed during the fall surveys. Width ranges from 4.8 to 40.0 m and water depths range from 0.1 to over 1.6 m. The upper stretch is mainly riffle-run, while the lower stretch consists mainly of deeper runs and pools. Substrates appeared to consist of mainly cobble and boulder in swift-flowing habitats and fines or sand in slower moving habitats. No redds were observed and no areas of preferable Atlantic salmon spawning habitat were observed in the upper and lower reach; however, these observations were limited by visibility. Three AOIs were identified to survey during low flow conditions. Overall, the physical habitat characteristics are suitable for various life stages of salmonids, although water quality (specifically pH) may limit the overall suitability of the habitat for salmonids to carry out their life processes.

The upper reach of Moose River is the most similar to the middle reach, as it contains primarily riffle-run habitats, predominantly coarse substrates (i.e., cobble/boulder substrates) and similar riparian forest cover (Stantec 2020). Overall, water temperature and pH likely are the biggest determinants in the quality of habitat for all life stages of Atlantic salmon and brook trout.
